Binary Underline

<u>Designing for relatively hard materials</u> that do not deform too much <u>is</u> commonly <u>handled</u> <u>by software that calculates</u> and optimizes <u>structures</u> using mathematical models that are well understood and easily applied. But there is <u>an expanding class of design challenges</u> <u>for things that incorporate soft materials</u> -- biological materials, engineered tissues, membranes, and even shape-shifting fluids that respond to electromagnetic fields. <u>Predicting how</u> these <u>soft</u> and fluidic <u>materials respond to forces is more challenging</u> than predicting the behavior of hard materials. <u>Real world applications</u> can <u>include design of artificial hearts</u> and <u>heart valves or robot materials</u> that mimic flesh and soft tissue.

To meet this challenge, a team of <u>Tufts researchers</u> led by Tim Atherton, professor of physics, <u>created Morpho</u>, an open-source programmable environment that enables <u>researchers</u> and engineers to solve shape optimization problems for soft materials. <u>The software</u> recently described in Nature Computational Science <u>is meant to be easy to use</u>, free to use, <u>and applicable</u> to a broad range of scenarios. Among the team developing the software were <u>James Adler</u>, professor of mathematics, <u>and Chaitanya Joshi</u>, postdoctoral scholar in physics.
